

The **Bells** is a sequencer that provides 12 bell ringing methods with tempo and jitter controls, quantised to six different scales.

- It sends a w/oct pitch sequence and synchronised pulse to control the oscillators or other inputs that could respond to permutation patterns, and optionally plays the methods using bell samples.

- Its parameters are controllable during playback and in a setup mode, accessible by holding Z down while turning the knob.

Main: tempo / z: method selection

X: jitter / : clock divider

Y: covering tenor / z: scale selection

- Z switch controls the mode:

Down (hold): change settings

Middle: stop

Up: start

The Bells

Using The Bells card for the Workshop System

By James Saunders / v1, June 2026

PERMUTATION PATTERNS FOR EXTENDED SEQUENCES

The computer generates pitch sequences conforming to [change ringing methods](#).

Use some FM and a low pass filter to create a bell sound and run the output through a reverb to get the full cathedral ambience (although the bells are often louder from outside).

Try adding some jitter for more authentic rhythmic instability, and add a [covering tenor](#) bell to end each line with the root note. There are six scales to choose from, and the key can be adjusted by tuning the oscillator.

The audio out provides sampled bell playback for up to six bells. Patch to two channels or combine using stackcables.

Experiment with extreme tempo differences and use the v/oct to control permutation processes in other parameters.
